## 1. SCOPE

- 1.1. This document contains the Reliability Prediction and Derating for the PMI Model RFFD-618-730049 FILTER DETECTOR. This reliability prediction has been done according to RF, FILTER DETECTOR ASSY drawing number 730049. As specified the reliability prediction is done in accordance with MIL-HDBK-217F and CHANGE NOTICE 1 and 2. In addition to the reliability prediction, all parts have been derated according to RADC-TR-72-177 level II. The specifications and stresses of each component are detailed in this document.

## 2. RELIABILITY PREDICTION

- 2.1. The failure rate of each individual component used in the Filter Detector was evaluated by using the specifications contained in RF, FILTER DETECTOR ASSY drawing number 730049 together with the individual component manufacturers specifications and the values given in MIL-HDBK-217F together with change notices 1 and 2.
- 2.2. Each components predicted failures per million hours at 95 deg C were then multiplied by the number of components used The failure rates of all components were then summed to form the total predicted failure rate.
- 2.3. The overall predicted failure rate of about 5 failures per million hours (FPMH) is within the maximum of 9 FPMH as specified in 730049 point 3.7.1.
- 2.4. The equations and details of the individual components failure rate calculations are included in Appendix A.

| PART NAME                            | Part References                | No parts | Individual Failure Rate<br>Failures per million<br>hours | Combined Failure Rate<br>Failures per million<br>hours |

### 3. COMPONENT PART DERATING

- 3.1. The electrical and thermal stresses of each component have been evaluated using the specifications contained in RF, FILTER DETECTOR ASSY drawing number 730049 together with the individual component manufacturers specifications. The derating as specified in RADC-TR-72-177 level II.

| PART NAME          | Part References             | Rated | Level II | Design | Units |   |
|--------------------|-----------------------------|-------|----------|--------|-------|---|
| DETECTOR DIODE     | D1, D2                      | 175   | 125      | 110    | deg C | Junction Temperature                                |
|                    |                             | 4     | 2.8      | 0      | V     | Breakdown Voltage DC                                |

#### 4. CONCLUSIONS

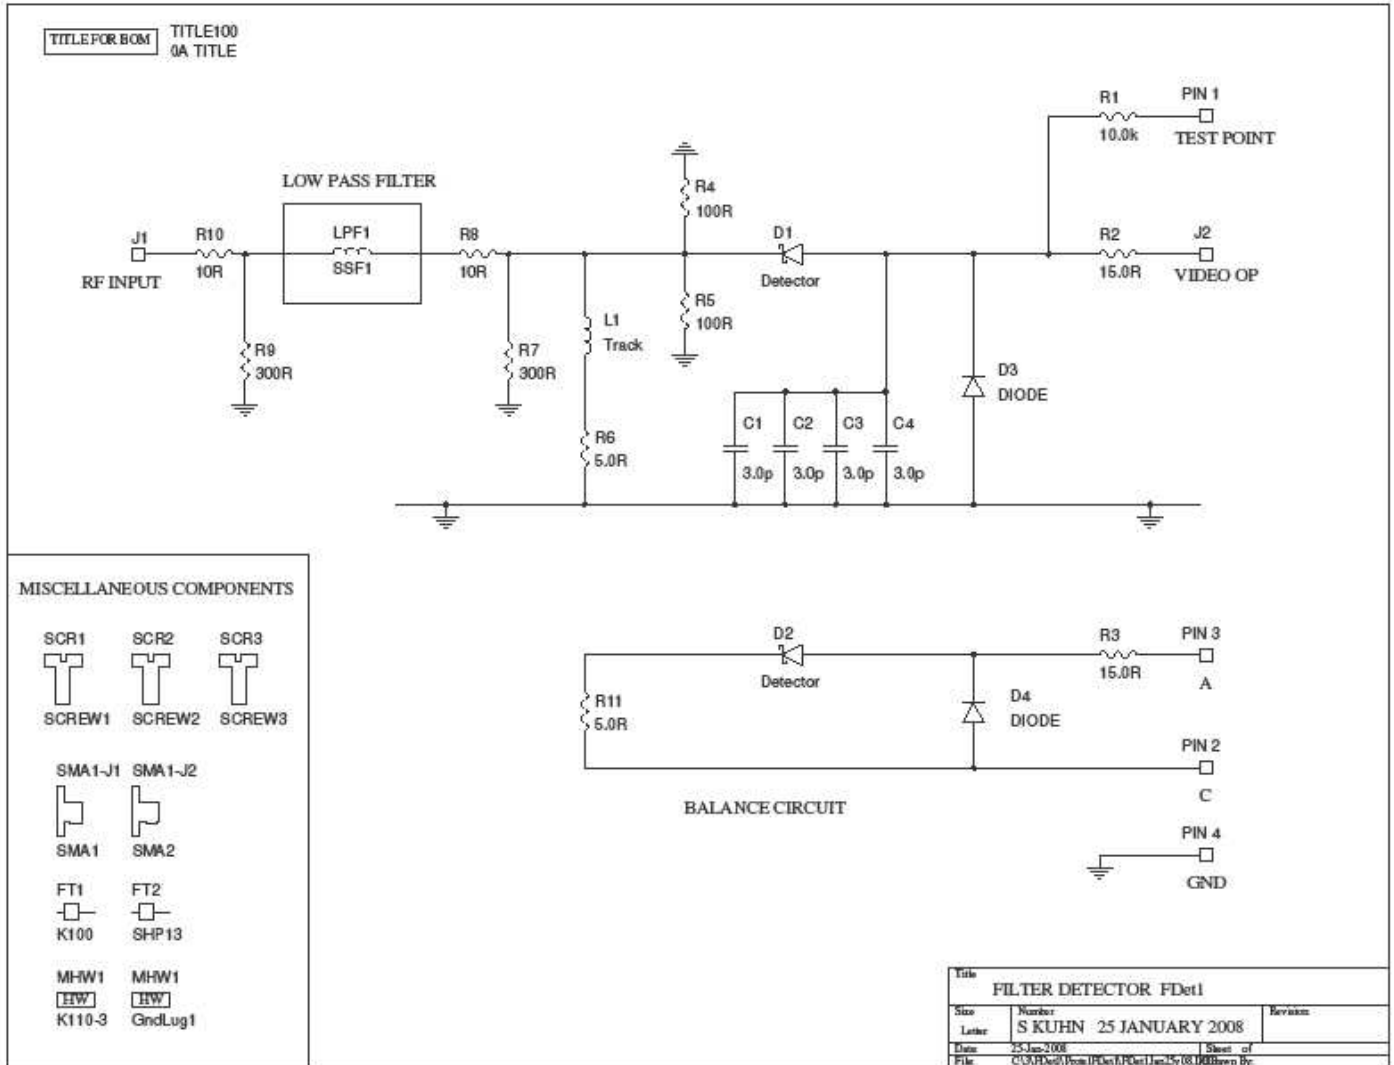

- 4.1. The Reliability Prediction for the Filter Detector was calculated according to the specifications contained in RF, FILTER DETECTOR ASSY drawing number 730049 together with the individual component manufacturers specifications and the values given in MIL-HDBK-217F and shown to be within the specified value. That is 5 FPMH versus a specified maximum of 9 FPMH. ( FPMH is failures all per million hours).
- 4.2. The stresses on all components has been shown to be within the derating limits as specified in RADC-TR-72-177 level II.
- 4.3. The conclusion is that this design meets the reliability and derating levels for the RF, FILTER DETECTOR ASSY drawing number 730049 .

## APPENDIX C: COMPONENT SPECIFICATIONS AND DATA

### Detector Diode

The schottky diodes are rated for operation to 26 GHz..  
 High reliability specified and tested.  
 Specified to operate from -65 to 175 deg C.

There are a few optional models of these diodes, we will construct detectors with at least the two versions shown here. We will then select the best choice to meet specifications.

#### Typical Parameters

#### Maximum Ratings

|  |                  |
|--|------------------|
| Pulse Power Incident at $T_A = 25^\circ\text{C}$ .....   | 1 W              |
| Pulse Width = 1 ms, $D_u = 0.001$  |                  |
| CW Power Dissipation at $T_A = 25^\circ\text{C}$ .....   | 150 mW           |
| <i>Measured in an infinite heat sink derated linearly to zero at maximum rated temperature</i> |                  |
| $T_{OPR}$ – Operating Temperature Range .....  | -65°C to +175 °C |
| $T_{STG}$ – Storage Temperature Range .....  | -65°C to +200°C  |

Notes: 3. Short duration test pulse used to minimize self-heating effect.

## BEAM LEAD CAPACITORS MIS

### Applications:

- DC Blocks
- Bypass
- Filters
- Matching

### Maximum Ratings:

|                       |        |
|-----------------------|--------|
| Storage Temperature   | -65    |
| to 150°C              |        |
| Operating Temperature | -65 to |
| 150 °C                |        |

### Notes:

1. Consult factory for special versions or high reliability screening
2. Dielectric Withstanding Voltage is 50V
3. Typical Temperature Coeff. = 55ppm/°C
4. Typical Insertion Loss = 0.04dB
5. All data at 25°C

## DISCRETE RESISTORS

### ELECTRICAL CHARACTERISTICS

Table 2

| CHARACTERISTICS                 | RC0603 1/10 W            |              |
|---------------------------------|--------------------------|--------------|
| Operating Temperature Range     | -55 °C to +155 °C        |              |
| Maximum Working Voltage         | 50 V                     |              |
| Maximum Overload Voltage        | 100 V                    |              |
| Dielectric Withstanding Voltage | 100 V                    |              |

ISO 9001:2000 CERTIFIED

FOR RESISTOR AREA LARGER THAN 1100 MIL<sup>2</sup>, THE RECOMMENDED POWER DISSIPATION AT 25°C AMBIENT IS AS FOLLOWS:

|                     |                                    |
|---------------------|------------------------------------|
| 10 ohms per square  | 0.190+ MilliWatts/mil <sup>2</sup> |
| 25 ohms per square  | 0.150+Milliwatts/mil <sup>2</sup>  |
| 50 ohms per square  | 0.138+Milliwatts/mil <sup>2</sup>  |
| 100 ohms per square | 0.100+Milliwatts/mil <sup>2</sup>  |
| 250 ohms per square | 0.090+Milliwatts/mil <sup>2</sup>  |

Maximum power dissipation depends on the ambient temperature, resistor element size and laminate/circuit board thermal properties. Dissipation improves with the use of natural heatsinks such as ground and power planes. Typical power dissipation for most Ohmega-Ply resistor designs operating at an ambient of less than 70 °C is approximately 1/10 to 1/8 Watt.

**Note:** Because of continuing product improvement, the above specifications and properties are subject to change. The information and data contained herein are based on tests to date, but no warranty thereof is given.

**VII) RELIABILITY TEST DATA AND SPECIFICATIONS**

- Ohmega-Ply<sup>®</sup> has been used in numerous applications for over 25 years; exhibiting excellent performance and dependability. Due to its absolute long-term reliability under a variety of severe environmental conditions, Ohmega-Ply<sup>®</sup> is used in numerous critical products (space-base, aerospace, avionics, etc.) where the utmost in reliability is required.
- The estimated failure rate for Ohmega-Ply<sup>®</sup> resistors is less than 0.001 resistor elements per 1 million operating hours (this is based on test results where over 1 trillion component hour have been accumulated without a field failure. Field failure is defined as resistor failure that is caused by the resistive material itself, and not other sources of printed circuit board failure (opens, shorts, defective base material, excessive power surges, improper operating conditions, etc.).
- Ohmega-Ply<sup>®</sup> Specifications and Properties

- In addition to in-house reliability testing at Ohmega Technologies, Inc., there have been numerous tests performed on Ohmega-Ply<sup>®</sup> by OEM customers and prospective customers. A few of them are:

#### Cray Research<sup>1</sup>

In a study of the stability of buried Ohmega-Ply<sup>®</sup> resistors used for ECL termination, Cray concluded that the Ohmega-Ply<sup>®</sup> resistors “would operate well beyond all normal voltages and temperatures, and there have been no reports of a resistor failure due to resistive material.” Cray Research also found that incorporating the Ohmega-Ply resistors into the internal plane of a multilayer board substantially improved the signal quality for high-speed devices. Cray Research has used Ohmega-Ply<sup>®</sup> in millions of multilayer circuit boards since 1982 with absolute field reliability of the resistive elements.

#### Alcatel Bell<sup>2</sup>

Researchers at Alcatel Bell tested Ohmega-Ply resistors for broadband (45 MHz–5GHz) telecom applications to characterize its impedance response and to compare the reliability of Ohmega-Ply to 0805 discrete thick film chip resistors, rated power 125 mW. A summary of their results is as follows.

Minimum and maximum parasitic effects extracted from measured characteristic of integrated resistor

### IBM<sup>3</sup>

IBM built and tested a numbers of evaluation boards that incorporated Ohmega-Ply<sup>®</sup> into number of internal layers of a multiplayer design. This effort was to see what effect, if any, there was on the assembly (and rework) process due to the embedded resistors. In addition, standard environmental stress tests were performed (including thermal cycling, thermal shock, vibration testing and torque testing). The findings of their published report showed “no significant resistance change on the resistors from the assembly process and stress test”.

### Unisys<sup>4</sup>

In evaluating the long term drift characteristics of Ohmega-Ply<sup>®</sup> on high Tg, low DC substrate, Unisys concluded that powered (22 mA), Ni-P buried resistors, fabricated using ammoniacal etch process and fully aqueous resist, when placed in a 55 °C cabinet environment, will drift < 2 % in 100,000 hours (11.4 years).

### Dassault<sup>5</sup>

Dassault Electronique did a 2 year study of Ohmega-Ply<sup>®</sup> for an active phased array antenna (X-band). The resistors were used in a stripline configuration a PTFE substrate (Rogers RT Duroid<sup>®</sup> 60002 and fusion bonded inside a multilayer package). The Ohmega-Ply<sup>®</sup> was compared to chip resistors and screen printed polymer inks. Ohmega-Ply<sup>®</sup> was selected for use due to superior tolerance and stability (compared to printed polymer inks) and space saving, parasitic reduction, and solder joint removal (compared to chip resistors). The results of testing are as follows:

| Etching Tolerance | Minimum Resistor Width | Tolerance After Fusion Bonding | Influence of Ohmega-Ply Foil Layer on Microwave Properties | Shift of Resistor Values After 500 Thermal Cycles (-55°C, +125°C) | Thermal Coefficient of Resistance Within the Range (-55°C, +125°C) | Power Handling | No shift in microwave performance of two ports power divider, when Ohmega Foil Technology is tested under the following conditions:   |
|-------------------|------------------------|--------------------------------|--|---|--|----------------|---|
| 5%                | 200 μ m                | 7%                             | NO   | Microstrip: +2%<br>Stripline: +3%                                 | Microstrip: ±6%<br>Stripline: ±7%                                  | 300 mW         | <ul style="list-style-type: none"> <li>• 500 thermal cycles (-55°C, +125°C)</li> <li>• 500 hours at 125°C</li> <li>• 40 days 40°C, 95% HR</li> <li>• 48 hours salt spray</li> </ul> |

**Rogers Corporation**<sup>6</sup>

In an internal study, Rogers evaluated Ohmega-Ply<sup>®</sup> resistors on Kapton<sup>®</sup> /Pyralux<sup>®</sup>. They found the following change in a resistor that was 0.25" x 4.0" in size with a flex radius of 0.25" (the flex rate was 10 cycles/minute):

| Number of Flex Cycles | % Change in Resistance |
|-----------------------|------------------------|
| 150                   | 0.5                    |
| 1,500                 | 6.1                    |
| 10,000                | 25.5                   |

When a cover film or conformal coating was placed over the resistors (or, the resistors were multilayered on an internal plane of circuitry), and flexed up to 250,000 cycles, there was no significant change in resistance.

## Ωmega Design Parameters for Optimum Long Term Stability

Omega Technologies, Inc.

### As a Function for Resistor Operating Temperature

*Long-term reliability is a function of operating temperature.* Like most electronic components, operating temperature (ambient temperature + temperature rise) is one of the most important factors that determine power rating of the component. As more power is dissipated through the resistors, the temperature of the resistor film increases which makes it more susceptible to thermal oxidation. Stability is measured by the change of resistance with aging. The figure below illustrates the relationship between different operating temperatures and change of resistance with respect to time.

Because the resistor film is a part of laminate, the physical and thermal characteristics of the substrate become major considerations. The heat dissipation of resistor films depends on:

1. The size (area) of the resistor
2. The circuit thickness and material type
3. The circuit configuration (clad/unclad)
4. ambient temperature
5. The thermal conductivity of the substrate
6. Additional system cooling (e.g. air-cooling, other heat sinking, etc.)

## **BURIED RESISTOR BURN-IN TRAYS**

### **GENERAL OVERVIEW**

Stressing the semi-conductor junctions can accelerate failure modes in integrated circuits. This stress usually takes the form of applying the rated, or just slightly above rated, voltages to the part while it is elevated to a higher than rated temperature. The parts are subsequently tested and the failures weeded out. This eliminates the phenomena of higher than normal failure rates early in the life cycle of a part, known as "infant mortality".

In order to ensure that all the parts see the required voltage, in the event of a single part failing with a short circuit, resistors are used to isolate each pin on each part from the common excitation signal. Since the excitation signal, whether DC or AC voltage, will drive the equivalent pins on each part, a short circuit on one part would jeopardize the integrity of the full burn-in on all the other parts.

IC's may have 16 isolated pins, thus requiring 16 eighth or quarter watt resistors per pin. These resistors take up valuable real estate on the burn-in trays. So much so that a tray with no isolation may hold 240 parts while a tray with full isolation may only hold 130 parts.

Utilizing Ohmega-Ply® and other modern printed circuit board design and fabrication techniques, a burn-in tray may be manufactured with the same density as a non-isolated tray, but with each pin fully isolated with the equivalent of an eighth watt resistor. A significant number of tray hours have already been experienced with no detrimental effects.

Trays were designed with multilayer polyimide construction for 125-150 degrees C continuous operation. Power dissipation per tray was limited to 75 watts based on system constraints. Testing has been accomplished on samples of the initial production run primarily to determine the effects of thermal shock and thermal soaking on the multilayer structure and resistor values.

Thermal Shock - MIL-STD-202, Method 107, Condition F, was followed for 50 cycles. This consisted of cycling from -65 to +150 degrees C holding at each temperature for 15 minutes and transferring in less than 2 minutes. There was absolutely no evidence of measling, blistering, or delamination. Further none of the 60 measured resistors changed in value.

---

Thermal Soak - Two sets of samples, one powered to 10 watts per square inch, the other powered to 1 watt per square inch were immersed in a 160 degree C environment in excess of 4,400 hours. Inasmuch as these are isolation and not precision resistors, design tolerances of +/- 20 percent are reasonable and achievable with this technique.

Data Sheet  
1.5000

## RT/duroid® 5870 /5880 High Frequency Laminates

### Features:

- Lowest electrical loss for reinforced PTFE material.
- Low moisture absorption.
- Isotropic
- Uniform electrical properties over frequency.
- Excellent chemical resistance.

### Some Typical Applications:

- Commercial Airline Telephones
- Microstrip and Stripline Circuits
- Millimeter Wave Applications
- Military Radar Systems
- Missile Guidance Systems
- Point to Point Digital Radio Antennas

RT/duroid® 5870 and 5880 glass microfiber reinforced PTFE composites are designed for exacting stripline and microstrip circuit applications.

Glass reinforcing microfibers are randomly oriented to maximize benefits of fiber reinforcement in the directions most valuable to circuit producers and in the final circuit application.

The dielectric constant of RT/duroid 5870 and 5880 laminates is uniform from panel to panel and is constant over a wide frequency range. Its low dissipation factor extends the usefulness of RT/duroid 5870 and 5880 to Ku-band and above.

RT/duroid 5870 and 5880 laminates are easily cut, sheared and machined to shape. They are resistant to all solvents and reagents, hot or cold, normally used in etching printed circuits or in plating edges and holes.

Normally supplied as a laminate with electrodeposited copper of  $\frac{1}{4}$  to 2 ounces/ft.<sup>2</sup> (8 to 70 $\mu$ m) on both sides, RT/duroid 5870 and 5880 composites can also be clad with rolled copper foil for more critical electrical applications. Cladding with aluminum, copper or brass plate may also be specified.

When ordering RT/duroid 5870 and 5880 laminates, it is important to specify dielectric thickness, tolerance, rolled or electrodeposited copper foil, and weight of copper foil required.

The information in this data sheet is intended to assist you in designing with Rogers' circuit material laminates. It is not intended to and does not create any warranties express or implied, including any warranty of merchantability or fitness for a particular purpose or that the results shown on this data sheet will be achieved by a user for a particular purpose. The user should determine the suitability of Rogers' circuit material laminates for each application.

The world runs better with Rogers.™

**HERMETIC FEEDTHRU**

PATENTED  
 US Patent No. 4,841,101  
 Canada Patent No. 1,318,371

ALUMINUM COMPATIBLE

Designed specifically for use in aluminum housings, our feedthrus will provide highly reliable hermetic sealing in cyclic military and processing temperature environments, when installed in accordance with recommended application data. Our feedthrus will also minimize assembly time and enhance solder joint quality.

Example Part No: SHP9815-075R-125-01

- NOTES:
- (1) Seals of any desired geometry can be provided. Contact us for your special requirements.
  - (2) Standard plating for ASTM-F15 is 50 microinches minimum GOLD per MIL-G-45204, Type III, Grade A over 100-200 microinches NICKEL per MIL-C-26074. Plating thickness is measured on pin.
  - (3) Standard plating for STEEL is 50 microinches minimum GOLD per MIL-G-45204, Type III, Grade A over 200-400 microinches NICKEL per MIL-C-26074. Plating thickness is measured on pin.
  - (4) Standard pin termination is straight-cut (radius on L1 end on 50 Ω). Special pin terminations are also available (see page 3).
  - (5) Insert desired pin diameter in thousandths, in series.
  - (6) RF feedthrus are stocked with various standard L1 lead lengths for quicker delivery. Contact us for details.
  - (7) See Bulletin 200 for solder preforms.
  - (8) ±.003 on 50 Ω

All dimensions are inches.
